## PHOSPHATASES WITH IMPROVED PHYTASE ACTIVITY

The present application claims the benefit of U.S. Provisional Patent  
5 Application Serial No. 60/127,032, filed March 31, 1999.

### BACKGROUND OF THE INVENTION

Phytases are *myo*-inositol hexakisphosphate phosphohydrolases that  
10 catalyze the stepwise removal of inorganic orthophosphate from phytate (*myo*-  
inositol hexakisphosphate) (1). There are two types of phytases. One is called 3-  
phytase (EC.3.1.3.8) which initiates the removal of phosphate groups at the  
positions 1 and 3 of the *myo*-inositol ring. The other is called 6-phytase  
(EC.3.1.3.26) which first frees the phosphate at the position 6 of the ring. While  
15 no phytase has been identified from animal tissues, plants usually contain 6-  
phytases and a broad range of microorganisms, including bacteria, filamentous  
fungi, and yeast, produce 3-phytases (2-9). Because over 70% of the total  
phosphorus in foods or feeds of plant origin is in the form of phytate that is poorly  
available to simple-stomached animals and humans, phytases are of great uses in  
20 improving mineral nutrition of these species (10-16). Supplemental microbial  
phytases in diets for swine and poultry effectively enhance bioavailability of  
phytate phosphorus and reduce the need for inorganic phosphorus  
supplementation (11-15), resulting less phosphorus pollution in areas of intensive  
animal production (8-15). However, a relatively high level of phytase  
25 supplementation is necessary in animal diets (10-16), because a considerable  
amount of the enzyme is degraded in stomach and small intestine (13), probably  
by proteolysis of pepsin and trypsin. Meanwhile, the proteolytic profiles of  
various phytases were not studied. Clearly, a better understanding of their  
sensitivities to trypsin and pepsin hydrolysis could be helpful for improving the  
30 nutritional value of phytases. *Aspergillus niger* phytase gene (*phyA*) has been  
overexpressed in its original host (17) and the recombinant enzyme (r-PhyA, EC  
3.1.3.8) has been used in animal diets as a commercial phytase (13, 14). This  
enzyme is a glycoprotein of approximately 80 kDa. *Escherichia coli* pH 2.5 acid  
phosphatase gene (*appA*) has also been characterized (18, 19). Animal

- 2 -

experiments have demonstrated that the recombinant enzyme (r-AppA, EC: 3.1.3.2) is as effective as r-PhyA in releasing phytate phosphorus in animal diets (14).

But, expenses of the limited available commercial phytase supply and the activity instability of the enzyme to heat of feed pelleting preclude its practical use in animal industry. Therefore, there is a need for enzymes which have a high level of phytase activity and a high level of stability for use in animal feed.

### SUMMARY OF THE INVENTION

10

The present invention provides a phosphatase fragment having improved phytase activity. A fragment of a phosphatase having increased phytase activity is produced by treating the phosphatase with a protease.

The invention further provides a recombinant gene encoding a phosphatase fragment having improved phytase activity. The vector consists of a promoter, a coding region encoding the phosphatase fragment, and a terminator.

In another embodiment, the invention provides a method of increasing the phytase activity of phosphatase by treating the phosphatase with a protease.

The invention also provides a phosphatase having improved phytase activity, which has an amino acid sequence as shown in SEQ. ID No. 1.

20

### BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 shows the change in phytase activity after protease digestion.

Figure 1A shows phytase activity changes of r-PhyA and r-AppA incubated with different ratios of trypsin/protein (w/w) ( $r = 0.001, 0.005, 0.01, \text{ and } 0.025$ ).

Symbols: r-PhyA (■) and r-AppA (●). The results are the mean  $\pm$  SEM from five independent experiments. \*indicates statistical significance ( $P < 0.01$ ) versus untreated r-PhyA or r-AppA control. Figure 1B shows phytase activity changes of

r-PhyA and r-AppA incubated with different ratios of pepsin/protein (w/w) ( $r = 0.001, 0.002, 0.005, \text{ and } 0.01$ ). Symbols: r-PhyA (□) and r-AppA (○). The results are the mean  $\pm$  SEM from seven independent experiments. \*indicates statistical significance ( $P < 0.01$ ) versus untreated r-PhyA or r-AppA control.

30

Figure 2 shows residual phytase activity of r-PhyA and r-AppA after trypsin or pepsin hydrolysis during a time course (0, 1, 5, 30, and 120 min). Symbols: trypsin-digested r-PhyA (■) or r-AppA (●); pepsin-digested r-PhyA (□) and r-AppA (○). The ratio of trypsin/phytase (w/w) used was:  $r = 0.01$  (w/w). The ratio of pepsin/phytase used was:  $r = 0.005$ . The results are the mean  $\pm$  SEM from six independent experiments. \*indicates statistical significance ( $P < 0.01$ ) versus untreated r-PhyA or r-AppA control.

Figure 3 shows the results of SDS-polyacrylamide gel electrophoresis of r-AppA (12%, Panel A) or r-PhyA (20%, Panel B) digested products by different amounts of trypsin ( $r = 0.001, 0.005, 0.01, \text{ and } 0.025, (w/w)$ ). Proteins were stained using Coomassie blue. T: trypsin control, C: purified r-AppA (Panel A) or r-PhyA (Panel B). The protein marker (M) is a 10 kDa ladder [10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, and 200 kDa] (Gibco). The results are representative from four independent experiments.

Figure 4 shows the results from SDS-polyacrylamide gel (20%) electrophoresis of r-AppA (Figure 4A) or r-PhyA (Figure 4B) digested products by different amounts of pepsin ( $r = 0.001, 0.002, 0.005, \text{ and } 0.01, (w/w)$ ). Proteins were stained using Coomassie blue. T: trypsin control, C: purified r-AppA (Figure 4A) or r-PhyA (Figure 4B). The protein marker (M) is a 10 kDa ladder [10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, and 200 kDa] (Gibco). The results are representative from six independent experiments.

Figure 5 shows the amounts of inorganic phosphorus (iP) released from soybean meal by r-PhyA and r-AppA incubated with different concentrations of trypsin ( $r = 0.001, 0.005, 0.01, \text{ and } 0.025, w/w$ ) (Figure 5A), or pepsin ( $r = 0.001, 0.002, 0.005, \text{ and } 0.01$ ) (Figure 5B). Symbols: r-AppA (■), r-PhyA (□). The results are the mean SEM from three independent experiments. \*indicates statistical significance ( $P < 0.01$ ) versus untreated r-AppA or r-PhyA control.

Figure 6 shows the nucleotide sequence of the *appA2* gene and its deduced amino acid sequence. The untranslated region is indicated by lowercase letters. The underlined sequences are the primers used to amplify *appA2* (Pfl: 1-22, and K2: 1468-1490), *appA2* (E2: 243-252, and K2: 1468-1490). Potential N-glycosylation sites are boxed. The sequence of *appA2* has been transmitted to Genebank data library with accession number 250016.

- 4 -

Figure 7 is a time course of extracellular phytase ( $\square$ ) and acid phosphatase (O) activities, and CIPPA2 mRNA expression ( $\blacktriangle$ ) in *Pichia pastoris* transformed with *appA2* after induction. Results are expressed as the mean  $\pm$  SEM from three experiments.

5        Figure 8 shows a northern blot analysis of *appA2* mRNA expression in *Pichia pastoris* transformed with *appA2* after induction (Figure 8A). Hybridization was realized using [ $\alpha$ - $^{32}$ P] labeled *appA2* as a probe. Twenty  $\mu$ g of total RNA was loaded per lane. Panel B represents the equal RNA loading visualized by the yeast rRNA under UV.

10        Figure 9 shows the pH dependence of the enzymatic activity at 37°C of the purified r-*appA2* ( $\bullet$ ), r-*appA* ( $\blacktriangle$ ), and r-*phyA* ( $\square$ ) with sodium phytate as the substrate. Buffers: pH 1.5-4.5, 0.2M glycine-HCl; pH 5.5-7.5, 0.2 M citrate; pH 8.5-11, 0.2 M Tris-HCl. Results are expressed as the mean SEM from three experiments.

15        Figure 10 shows a non-denaturing gel (15%) electrophoresis analysis of the remaining acid phosphatase activity of r-*appA2* after incubated at different temperatures for 20 min. After the heat treatment, the samples were put on ice for 5 min before being loaded onto the gel (200  $\mu$ g protein/lane).

20        Figure 11 shows the hydrolysis of phytate phosphorus in soybean meal by different amounts (100, 300, 600, and 900 PU) of purified r-*appA2* ( $\bullet$ ), r-*appA* ( $\blacktriangle$ ), and r-*phyA* ( $\square$ ) enzymes. \* indicates significant differences ( $P < 0.05$ ) between r-*appA2* and other two enzymes. Results are expressed as the mean  $\pm$  SEM from three experiments.

## 25                    DETAILED DESCRIPTION OF THE INVENTION

The present invention provides phosphatases having improved phytase activity.

30        One embodiment of the invention provides a phosphatase fragment having improved phytase activity. The phosphatase is treated with a protease and fragments having phosphatase activity are selected. As discussed in further detail below, these fragments, have improved phytase activity compared to the full length peptide.

- 5 -

In a preferred embodiment, the protease is pepsin.

In addition to producing the active fragment by proteolysis of the full length peptide, the present invention also provides a recombinant gene having a promoter, a coding region encoding the phosphatase fragment according to claim 1, and a terminator. The recombinant gene can be used to express the truncated product directly.

The improved phosphatases can be used in animal feed to improve the accessibility of phosphate to the animal.

In addition to the phosphatase, the invention provides a method of increasing the phytase activity of phosphatase by treating the phosphatase with a protease.

In another embodiment, the invention provides a phosphatase having improved phytase activity, which has an amino acid sequence as shown in SEQ. ID No. 1 as shown in Figure 6.

Preferably, the protein or polypeptide with phytase activity is secreted by the cell into growth media. This allows for higher expression levels and easier isolation of the product. The protein or polypeptide with phytase activity is coupled to a signal sequence capable of directing the protein out of the cell. Preferably, the signal sequence is cleaved from the protein.

In a preferred embodiment, the heterologous gene, which encodes a protein or polypeptide with phytase activity, is spliced in frame with a transcriptional enhancer element.

A preferred phosphatase is encoded by the *appA* gene of *E. coli*. The gene, originally defined as *E. coli* periplasmic phosphoanhydride phosphohydrolase (*appA*) gene, contains 1,298 nucleotides (GeneBank accession number: M58708). The gene was first found to code for an acid phosphatase protein of optimal pH of 2.5 (EcAP) in *E. coli*. The acid phosphatase is a monomer with a molecular mass of 44,644 daltons. Mature EcAP contains 410 amino acids (18). Ostanin, et al. overexpressed *appA* in *E. coli* BL21 using a pT7 vector and increased its acid phosphatase activity by approximately 400-folds (440 mU/mg protein) (20). The product of the *appA* gene was not previously known to have phytase activity.

- 6 -

The phosphatase can be expressed in any prokaryotic or eukaryotic expression system. A variety of host-vector systems may be utilized to express the protein-encoding sequence(s). Preferred vectors include a viral vector, plasmid, cosmid or an oligonucleotide. Primarily, the vector system must be compatible with the host cell used. Host-vector systems include but are not limited to the following: bacteria transformed with bacteriophage DNA, plasmid DNA, or cosmid DNA; microorganisms such as yeast containing yeast vectors; mammalian cell systems infected with virus (e.g., vaccinia virus, adenovirus, etc.); insect cell systems infected with virus (e.g., baculovirus); and plant cells infected by bacteria. The expression elements of these vectors vary in their strength and specificities. Depending upon the host-vector system utilized, any one of a number of suitable transcription and translation elements can be used.

Preferred hosts for expressing phosphatase include fungal cells, including species of yeast or filamentous fungi, may be used as host cells in accordance with the present invention. Preferred yeast host cells include different strains of *Saccharomyces cerevisiae*. Other yeasts like *Kluyveromyces*, *Torulaspora*, and *Schizosaccharomyces* can also be used. In a preferred embodiment, the yeast strain used to overexpress the protein is *Saccharomyces cerevisiae*. Filamentous fungi host cells include *Aspergillus* and *Neurospora*.

In another embodiment of the present invention, the yeast strain is a methylotrophic yeast strain. Methylotrophic yeast are those yeast genera capable of utilizing methanol as a carbon source for the production of the energy resources necessary to maintain cellular function and containing a gene for the expression of alcohol oxidase. Typical methylotrophic yeasts include members of the genera *Pichia*, *Hansenula*, *Torulopsis*, *Candida*, and *Karwinskia*. These yeast genera can use methanol as a sole carbon source. In a preferred embodiment, the methylotrophic yeast strain is *Pichia pastoris*.

A preferred embodiment of the invention is a protein or polypeptide having phytase activity with optimum activity in a temperature range of 57 to 65°C. A more preferred embodiment is a protein or polypeptide having phytase activity, where its temperature range for optimum activity is from 58 to 62°C.

Yet another preferred embodiment is a protein or polypeptide having phytase activity where the protein retains at least 40% of its activity after heating

- 7 -

the protein for 15 minutes at 80°C. More preferred is a protein or polypeptide having phytase activity where the protein retains at least 60% of its activity after heating the protein for 15 minutes at 60°C.

Purified protein may be obtained by several methods. The protein or  
5 polypeptide of the present invention is preferably produced in purified form (preferably at least about 80%, more preferably 90%, pure) by conventional techniques. Typically, the protein or polypeptide of the present invention is secreted into the growth medium of recombinant host cells. Alternatively, the protein or polypeptide of the present invention is produced but not secreted into  
10 growth medium. In such cases, to isolate the protein, the host cell carrying a recombinant plasmid is propagated, lysed by sonication, heat, or chemical treatment, and the homogenate is centrifuged to remove cell debris. The supernatant is then subjected to sequential ammonium sulfate precipitation. The fraction containing the polypeptide or protein of the present invention is subjected  
15 to gel filtration in an appropriately sized dextran or polyacrylamide column to separate the proteins. If necessary, the protein fraction may be further purified by HPLC.

The present invention also provides a yeast strain having a heterologous gene which encodes a protein or polypeptide with phytase activity. The  
20 heterologous gene should be functionally linked to a promoter capable of expressing phytase in yeast and followed by a transcriptional terminator.

Yet another aspect of the invention is a vector for expressing phytase in a host. The vector carries a phosphatase gene which encodes a protein or polypeptide with phytase activity.

25 For cloning into yeast, the gene can be cloned into any vector which replicates autonomously or integrates into the genome of yeast. The copy number of autonomously replicating plasmids, e.g. YEp plasmids may be high, but their mitotic stability may be insufficient (48). They may contain the 2  $\mu$ -plasmid sequence responsible for autonomous replication, and an *E. coli* sequence  
30 responsible for replication in *E. coli*. The vectors preferably contain a genetic marker for selection of yeast transformants, and an antibiotic resistance gene for selection in *E. coli*. The episomal vectors containing the ARS and CEN sequences occur as a single copy per cell, and they are more stable than the YEp

- 8 -

vectors. Integrative vectors are used when a DNA fragment is integrated as one or multiple copies into the yeast genome. In this case, the recombinant DNA is stable and no selection is needed (49-51). Some vectors have an origin of replication, which functions in the selected host cell. Suitable origins of replication include 2 $\mu$ , ARS1, and 25 $\mu$ M. The vectors have restriction endonuclease sites for insertion of the fusion gene and promoter sequences, and selection markers. The vectors may be modified by removal or addition of restriction sites, or removal of other unwanted nucleotides.

The phytase gene can be placed under the control of any promoter (52).

One can choose a constitutive or regulated yeast promoter. Suitable promoter sequences for yeast vectors include, among others, promoters for metallothionein, 3-phosphoglycerate kinase (53) or other glycolytic enzymes (54), such as enolase, glyceraldehyde-3-phosphate dehydrogenase, hexokinase, pyruvate decarboxylase, phosphofructokinase, glucose-6-phosphate isomerase, 3-phosphoglycerate mutase, pyruvate kinase, triosephosphate isomerase, phosphoglucose isomerase, and glucokinase. Other suitable vectors and promoters for use in yeast expression are further described in EP A-73,657 to Hitzeman, which is hereby incorporated by reference. Another alternative is the glucose-repressible ADH2 promoter (56, 57), which are hereby incorporated by reference.

One can choose a constitutive or regulated yeast promoter. The strong promoters of e.g., phosphoglycerate kinase (PGK) gene, other genes encoding glycolytic enzymes, and the alpha -factor gene, are constitutive. When a constitutive promoter is used, the product is synthesized during cell growth. The ADH2 promoter is regulated with ethanol and glucose, the GAL-1-10 and GAL7 promoters with galactose and glucose, the PHO5 promoter with phosphate, and the metallothioneine promoter with copper. The heat shock promoters, to which the HSP150 promoter belongs, are regulated by temperature. Hybrid promoters can also be used. A regulated promoter is used when continuous expression of the desired product is harmful for the host cells. Instead of yeast promoters, a strong prokaryotic promoter such as the T7 promoter, can be used, but in this case the yeast strain has to be transformed with a gene encoding the respective polymerase. For transcription termination, the HSP150 terminator, or any other functional terminator is used. Here, promoters and terminators are called control elements.

- 9 -

The present invention is not restricted to any specific vector, promoter, or terminator.

The vector may also carry a selectable marker. Selectable markers are often antibiotic resistance genes or genes capable of complementing strains of yeast having well characterized metabolic deficiencies, such as tryptophan or histidine deficient mutants. Preferred selectable markers include URA3, LEU2, HIS3, TRP1, HIS4, ARG4, or antibiotic resistance genes.

The vector may also have an origin of replication capable of replication in a bacterial cell. Manipulation of vectors is more efficient in bacterial strains. Preferred bacterial origin of replications are ColE1, Ori. or oriT.

A leader sequence either from the yeast or from phytase genes or other sources can be used to support the secretion of expressed phytase enzyme into the medium. The present invention is not restricted to any specific type of leader sequence or signal peptide.

Suitable leader sequences include the yeast alpha factor leader sequence, which may be employed to direct secretion of the phytase. The alpha factor leader sequence is often inserted between the promoter sequence and the structural gene sequence (58; U.S. Patent No. 4,546,082; and European published patent application No. 324,274, which are hereby incorporated by reference). Another suitable leader sequence is the *S. cerevisiae* MF alpha 1 (alpha-factor) is synthesized as a prepro form of 165 amino acids comprising signal-or prepeptide of 19 amino acids followed by a "leader" or propeptide of 64 amino acids, encompassing three N-linked glycosylation sites followed by (LysArg(Asp/Glu, Ala)2-3 alpha-factor)4 (58). The signal-leader part of the preproMF alpha 1 has been widely employed to obtain synthesis and secretion of heterologous proteins in *S. cerevisiae*. Use of signal/leader peptides homologous to yeast is known from U.S. Patent No. 4,546,082, European Patent Applications Nos. 116,201; 123,294; 123,544; 163,529; and 123,289 and DK Patent Application No. 3614/83, which are hereby incorporated by reference. In European Patent Application No. 123,289, which is hereby incorporated by reference, utilization of the *S. cerevisiae* a-factor precursor is described whereas WO 84/01153, which is hereby incorporated by reference, indicates utilization of the *Saccharomyces cerevisiae* invertase signal peptide, and German Patent Application DK 3614/83, which is

- 10 -

hereby incorporated by reference, indicates utilization of the *Saccharomyces cerevisiae* PH05 signal peptide for secretion of foreign proteins.

The alpha -factor signal-leader from *Saccharomyces cerevisiae* (MF alpha 1 or MF alpha 2) may also be utilized in the secretion process of expressed heterologous proteins in yeast (U.S. Patent No. 4,546,082, European Patent Applications Nos. 16,201; 123,294; 123 544; and 163,529, which are hereby incorporated by reference). By fusing a DNA sequence encoding the *S. cerevisiae* MF alpha 1 signal/ leader sequence at the 5' end of the gene for the desired protein secretion and processing of the desired protein was demonstrated.

10 The use of the mouse salivary amylase signal peptide (or a mutant thereof) to provide secretion of heterologous proteins expressed in yeast has been described in Published PCT Applications Nos. WO 89/02463 and WO 90/10075, which are hereby incorporated by reference.

U.S. Patent No. 5,726,038 describes the use of the signal peptide of the yeast aspartic protease 3, which is capable of providing improved secretion of proteins expressed in yeast. Other leader sequences suitable for facilitating secretion of recombinant polypeptides from yeast hosts are known to those of skill in the art. A leader sequence may be modified near its 3' end to contain one or more restriction sites. This will facilitate fusion of the leader sequence to the structural gene.

20

Yeast transformation protocols are known to those of skill in the art. One such protocol is described in Hinnen et al. (59). The Hinnen et al. protocol selects for Trp transformants in a selective medium, wherein the selective medium consists of 0.67% yeast nitrogen base, 0.5% casamino acids, 2% glucose, 10 µg/ml adenine and 20 µg/ml uracil.

25

The gene may be maintained on stable expression vector, an artificial chromosome, or by integration into the yeast host cell chromosome. Integration into the chromosome may be accomplished by cloning the phytase gene into a vector which will recombine into a yeast chromosome. Suitable vectors may include nucleotide sequences which are homologous to nucleotide sequences in the yeast chromosome. Alternatively, the phytase gene may be located between recombination sites, such as transposable elements, which can mobilize the gene into the chromosome.

30

- 11 -

The present invention also provides a method of producing phytase by providing an isolated phosphatase gene, which encodes a protein or polypeptide with phytase activity, and expressing the gene in host cell. The phosphatase preferably is a microbial phosphatase. In a more preferred embodiment, the microbial phosphatase is an *Escherichia coli* phosphatase. Also preferred are the microbial phosphatases, AppA and AppA2.

A method of converting phytate to inositol and inorganic phosphorus is also provided. An *appA* gene is isolated from an organism, using techniques well known in the art. A protein or polypeptide with phytase activity is then expressed from the gene in a host cell. The resulting protein or polypeptide is mixed or contacted with phytate. This technique is especially useful for treating phytate in food or animal feed.

The preferred *appA* gene is isolated from *Escherichia coli*.

While the phytase enzyme produced in a yeast system released phytate-P from corn and soy as effectively as the currently commercial phytase, it appeared to be more thermostable. This phytase overexpression system in yeast can be used to provide thermostable phytase for use in the food and feed industries.

## EXAMPLES

20

### **Example 1 - Materials and Methods for Examples 2-6**

*Expression of r-AppA.* The *appA* gene (Genebank accession number M58708) was obtained from *E. coli* BL21 strain transformed by an expression vector pAPPA1 (20). A 1.35 kb DNA fragment containing the coding region of *appA* was amplified by PCR following the manufacturer instructions (Perkin Elmer). Primers were derived from 5' and 3' regions of the nucleotide sequence (18), and include: E2 [forward: 242-252]:  
5'GGAATTCCAGAGTGAGCCGGA3' (SEQ. ID. No. 2) and K2 [reverse: 1468-1490]: 5'GGGGTACCTTACAACTGCACG3' (SEQ. ID. No. 3). These two primers were synthesized by the Cornell University Oligonucleotide Synthesis Facility (Ithaca, NY). The amplified product was sliced from a 1% agarose gel, and eluted with GENE CLEAN II kit (Bio101). The purified fragment was first

- 12 -

cloned into pGEM T-easy vector (Promega), and then inserted into the yeast expression vector pPicZ $\alpha$ A (Invitrogen) at *Eco*RI site. *E. coli* strain TOP10F' (Invitrogen) was used as an initial host to amplify these two constructs. The pPicZ $\alpha$ A vector containing *appA* was transformed into *P. pastoris* strain X33 by electroporation according to the manufacturer's instructions (Invitrogen). The transformed cells were plated into YPD-Zeocin agar medium and positive colonies were incubated in minimal media with glycerol (BMGY) for 24 h. When the yeast cell density reached  $2.5 \times 10^8$  cells/ml ( $OD_{600} = 5$ ), the cells were centrifuged and suspended in 0.5 % methanol medium (BMMY) to induce the *appA* gene expression. Total yeast genomic DNA was extracted from the transformed X33 cells after induction and used as a template to check the presence of the *appA* gene by PCR using the same primers as described above. The amplified DNA fragment was sequenced at the Cornell University DNA Services-Facility using Taq Cycle automated sequencing with Dye Deoxy terminators (Applied Biosystems, Forster City, CA).

*Purification of r-PhyA and r-AppA.* r-PhyA was obtained from BASF (Mt Olive, NJ). Both r-PhyA and r-AppA enzymes were initially suspended into 50 mM Tris-HCl, pH 7, and ammonium sulfate was added to 25% of saturation. After the mixture was centrifuged (25,000 g, 20 min), the supernatant was saved and ammonium sulfate was added to 75% of saturation. Then, the mixture was centrifuged (25,000 g, 20 min) and the pellet was suspended into 10 mL of 25 mM Tris-HCl, pH 7. The suspension was dialyzed overnight against the same buffer and loaded onto a DEAE-Sepharose column (Sigma) equilibrated with 25 mM Tris-HCl, pH 7. Proteins were diluted with 0.2 M NaCl, 25 mM Tris-HCl, pH 7 after the column was washed with 200 n-LL of 25 mM Tris-HCl, pH 7. All the collected fractions were assayed for phytase activity and protein concentration (21). The whole purification was conducted at 4°C, and the fractions were stored at -20°C before analysis.

*Proteolysis and protein electrophoresis.* The purified r-AppA and r-PhyA (2 mg/mL) were incubated with different amounts of pepsin and trypsin following the manufacturer instructions (Sigma). Pepsin (800 units/mg protein) and trypsin (1,500 BAEE units/mg protein) were dissolved into 10 mM HCl, pH 2 (0.1 mg/mL) and 80 mM ammonium bicarbonate, pH 7.5 (0.1 mg/mL), respectively.

- 13 -

One BAEE unit was defined as 0.001 absorbance change at 253 nm per minute at pH 7.6 and 25°C, with BAEE as a substrate. In a final volume of 100  $\mu$ L, 10  $\mu$ g of purified r-PhyA (0.1 PU) or r-AppA (0.08 PU) was incubated with trypsin or pepsin at protease/phytase (w/w) ratios ranging from 0.001 to 0.01, at 37°C for 1  
5 to 120 min. The reaction was stopped on ice and the pH of the mixture was adjusted to 8 for protein electrophoresis and phytase activity assay. The digested protein mixtures were analyzed by sodium dodecyl sulfate (SDS)-polyacrylamide or urea-SDS-polyacrylamide gel electrophoresis as previously described (22, 23).

*Phytase activity and hydrolysis of phytate phosphorus from soybean meal.*

10 Phytase activities of both r-PhyA and r-AppA, prior to or at various time points of proteolysis, were determined as previously described (24). The released inorganic phosphorus (iP) was assayed by the method of Chen et al. (25). One phytase unit (PU) was defined as the activity that releases 1  $\mu$ mol of iP from sodium phytate per minute at 37°C. To confirm the proteolytic effects of trypsin and pepsin on  
15 the residual activities of r-PhyA and r-AppA, the hydrolysis of phytate phosphorus from soybean meal by these two enzymes incubated with different amounts of trypsin or pepsin was monitored. In a 5 mL total reaction, 0.5 mg of the purified r-PhyA (5 PU) or r-AppA (4 PU) was incubated with 1 g soybean meal and pepsin in 10 mM HCl, pH 2.5 or trypsin in 0.2 M citrate, pH 6.8 at 37°C for 2 h. The  
20 released iP was determined as described above.

**Example 2 - Preparation of r-AppA and r-PhyA.**

Over 30 colonies of X33 transformed with the *appA* gene expressed  
25 extracellular phytase activity that hydrolyzes sodium phytate. Colony 26 had the highest activity (88 U/mL) and was chosen for further studies. After the r-PhyA and the r-AppA samples were eluted from the DEAE-Sepharose column, 45 fractions of 4 mL each were collected for both enzymes to assay for phytase activity. The fractions used for proteolysis had a specific phytase activity of 9.6  
30 and 8.1 U/mg of protein for the r-PhyA and r-AppA, respectively.

- 14 -

**Example 3 - Effects of Trypsin Digestion on the Phytase Activities of Both Enzymes.**

After 2 hour trypsin digestion, there were significant differences in the residual phytase activities between the r-PhyA and the r-AppA (Figure 1A). Although both enzymes retained more than 85% of their original activities at the trypsin/phytase ratios of 0.001 and 0.005, r-AppA lost 64 and 74% of its original activity at the ratio of 0.01 and 0.025, respectively. Meanwhile, r-PhyA lost only 14 and 23% of its original activity, respectively. Because of the apparent difference in sensitivities of these two enzymes to trypsin digestion at the ratio of 0.01, a time course study was conducted with this ratio. Up to 2 hour trypsin digestion, r-PhyA still retained 90% of its original activity (Figure 2). In contrast, r-AppA lost 64, 77, 87, and 95% of its original activity after 1, 5, 30, and 120 minute digestion, respectively.

**Example 4 - Effect of Pepsin Digestion on the Phytase Activities of Both Enzymes.**

After 2 hour pepsin digestion, the residual phytase activity of r-AppA was totally unexpected. At the ratios of 0.001 and 0.002, the phytase activity either remained unchanged or slightly increased. At the ratios of 0.005 and 0.01, the phytase activity was enhanced by 30% compared with the initial value. However, r-PhyA lost 58 and 77% of its original activity at these two high ratios (Figure IB). Because significantly different responses between r-PhyA and r-AppA at the ratio of 0.005, this ratio was used for a follow-up time course study. There was a stepwise increase in phytase activity along with time when the r-AppA was incubated with pepsin from 0 to 30 min. Thereafter no further increase was observed (Figure 2). However, r-PhyA lost 42, 73, 82, and 92% of its original activity after 1, 5, 30, and 120 minute incubation, respectively.

**Example 5 - SDS-polyacrylamide gel electrophoresis.**

When r-AppA was incubated with trypsin, the enzyme protein was degraded at the ratios above 0.01 and was invisible at the ratio of 0.025. There

- 15 -

was a major band of approximately 28 kDa, with several other bands between this band and the intact protein in the three low ratios of trypsin. However, that major band was clearly reduced and the other bands disappeared at the highest ratio of trypsin (Figure 3A). There were many intermediary bands when the r-PhyA was incubated with various amounts of trypsin and there were at least three visible bands at the highest ratio of trypsin (Figure 3B). A unique band of approximately 8.4 kDa was shown when r-AppA was incubated with pepsin at the ratio above 0.002 (Figure 4A). On the other hand, proteolysis of r-PhyA by various amounts of pepsin resulted in many diffused and smearing bands, in addition to a major fragment of approximately 14 kDa (Figure 4B).

**Example 6 - Effects of Proteolysis on Phytate-Phosphorus Hydrolysis by r-PhyA and r-AppA.**

When r-AppA was incubated with soybean meal and different amounts of trypsin for 2 h at 37°C, the reduction in iP released from soybean meal was 3, 13, 34, and 52%, at the ratio of 0.001, 0.005, 0.01, and 0.025, respectively (Figure 5A). Meanwhile, the reduction for r-PhyA at the same condition was 3, 6, 13, and 28%, respectively. Adding pepsin to r-AppA (ratio 0.005) and the soybean meal mixture resulted in approximately 30% increase in iP released from soybean meal, compared with the control (Figure 5B). In contrast, the same treatments produced more than 50% reduction in iP release by r-PhyA.

To date, there have been no specific data on sensitivities of microbial phytases to trypsin and pepsin. In this study, two partially purified recombinant phytases were exposed to single protease digestions, and measured the effects of proteolysis on their residual activities and their capacity of releasing phytate phosphorus from soybean meal. These results have demonstrated that r-PhyA is more resistant to trypsin and less resistant to pepsin than r-AppA. The proteolytic patterns of these two phytases, shown by SDS-PAGE analysis, are also distinctly different. Presumably, these different susceptibilities to proteases between r-PhyA and r-AppA may be associated with their characteristics of primary amino acid sequence and peptide folding, because there is a low homology (-15%) of amino acid sequences between these two enzymes (17, 18). However, caution

- 16 -

should be given in consideration of the molecular mechanism of phytase proteolysis, which is beyond the original scope of the present study. Recent progress in crystallization and (or) preliminary X-ray analysis of the phyA phytase (26) and an *E. coli* phytase (27) would help us in understanding the structural basis for their proteolytic responses.

Unexpectedly, r-AppA showed a 30% increase in residual phytase activity after pepsin digestion. Likewise, this enzyme also released 30% more iP from soybean meal in the presence of pepsin. From the SDS-PAGE analysis, r-AppA was clearly degraded into small peptides by pepsin along different periods of incubation. Likely, there may be potential pepsin resistant polypeptides with higher phytase activity than the intact r-AppA protein. Although the SDS-PAGE analysis did not offer us any specific information on such peptides, pepsin has been shown to convert natural or synthetic proteins in active polypeptides, such as converting porcine endothelin to active 21-residue endothelin (28). Pepsin may also modulate the structure and functions of certain proteins (29, 30). As mentioned above, the availability of the recent crystallization data on the phyA (26) and the *E. coli* phytases (27) would facilitate targeting site-directed mutageneses or deletions of the appA gene. Thereby, it may be possible to unveil the molecular mechanism for the increase of phytase activity of r-AppA associated with pepsin hydrolysis. In spite of the biochemical uncertainty of the pepsin resistant r-AppA peptides, this finding has a great nutritional implication. Because pepsin, a well described aspartic protease, is the major protease in the stomach (31), a pepsin resistant phytase polypeptides could allow us to supplement a low level of enzyme to the diets with sufficient activity. Thus, expense for use of dietary phytase in animal production will be reduced.

It is difficult to compare the activity levels of proteases used in the present study with those at the physiological conditions, because the *in vivo* concentrations of pepsin and trypsin have not been well described. An average trypsin activity of 20 to 25 U/mg of protein has been reported in the intestine of pig (32), which is much higher than the doses used herein. However, multiple levels of trypsin and pepsin were used, with 10 to 25 fold range differences between the lowest and highest levels. In addition, the iP release from soybean meal by r-AppA or r-PhyA was measured in the presence of pepsin or trypsin, a

simulated *in vivo* digestive condition. Although both r-AppA and r-PhyA were partially purified, all the data consistently point toward distinct responsive patterns of these two recombinant enzymes to pepsin and trypsin. Thus, this *in vitro* observation could be relevant to physiological conditions.

5

#### **Example 7 – Materials and Methods for Examples 8-12**

##### *Isolation and identification of phytase producing bacterium colonies.*

Colon contents were obtained from crossbreed Hampshire-Yorkshire-Duroc pigs  
10 (13 weeks of age) raised under confinement at Cornell University Swine Farm.  
These pigs were fed a practical corn-soybean meal diet. Immediately after the  
pigs were killed, the content of colon was removed by aseptic procedures and kept  
in anaerobic, sterile plastic bags. A 10 g sample was diluted with 190 ml of an  
anaerobic rumen fluid glucose medium in a 250 ml rubber-stoppered Erlenmeyer  
15 flask. The mixture was shaken vigorously for 3 min under a CO<sub>2</sub> atmosphere.  
Serial successive dilutions were made accordingly.

Diluted samples were cultured at 37°C for 3 days in a modified rumen  
fluid-glucose-cellobiose-Agar medium containing insoluble calcium phytate (43,  
44). Colonies with a clear zone were tested as a potential producer of intra and  
20 extracellular phytase activity. Phytase activity was measured using sodium  
phytate as a substrate (24). One phytase unit (PU) was defined as the activity that  
releases one  $\mu$ mole of inorganic phosphorus from sodium phytate per minute at  
37°C. Acid phosphatase activity was assayed using *p*-nitrophenyl phosphate (P-  
NPP) as a substrate according to the manufacturer instructions (Sigma, St Louis,  
25 MO). Identification of the selected colony was conducted in the Diagnostic  
Laboratory of Cornell Veterinary College (Ithaca, NY). Morphological and  
physiological characteristics of the isolated colony were determined by standard  
procedures.

*DNA amplification and sequencing.* Because the colony that produced the  
30 highest acid phosphatase and phytase activities was identified as an *E. coli* strain,  
primers derived from the DNA sequence of *E. coli* pH 2.5 acid phosphatase gene  
(*appA*, GeneBank Accession number 145283) (18) were used to isolate the gene.  
Primers Pfl [forward: 1-22]:

- 18 -

5'-TAAGGAGCAGAAACAATGTGGT-3' (SEQ. ID. No. 4), E2 [forward: 254-264]:

5'-GGAATTCCAGAGTGAGCCGGA-3' (SEQ. ID. No. 5), and K2 [reverse: 1468-1491]:

- 5 5'-GGGGTACCTTACAAACTGCACG-3' (SEQ. ID. No. 6) were synthesized at the Cornell University Oligonucleotide Synthesis Facility. The whole sequence and the coding region were amplified using [Pf1-K21 and [E2-K2] primers, respectively. The PCR reaction mixture (100  $\mu$ l,) contained 500 ng of genomic DNA as template, 100 pmole of each primer, 5 U of *AmpliTaq* DNA polymerase  
10 (Perkin Elmer, Norwalk, CT), 10 mM Tris-HCl pH 8.3, 50 mM KCl, 12.5 mM MgCl<sub>2</sub>, and 200  $\mu$ M each dNTPs (Promega, Madison, WI). The reaction was performed by the GeneAmp PCR system 2400 (Perkin Elmer). The thermal program included 1 cycle at 94°C (3 min), 30 cycles of [94°C (0.8 min), 54°C (1 min) and 72°C (2 min)] and 1 cycle at 72°C (10 min). Amplified PCR products  
15 were resolved by 1% low melting agarose (Gibco BRL, Grand Island, NY) gel electrophoresis. A gel slice containing the expected size band was excised and DNA was eluted with GENE CLEAN II kit (Bio101, Vista, CA). The PCR products were sequenced at the Cornell University DNA Service Facility using Taq Cycle automated sequencing with Dye Deoxy terminators (Applied  
20 Biosystems, Foster City, CA). Sequencing experiments were performed five times and the deduced amino sequence was aligned with other acid phosphatases and phytases using the Multi-align Program CLUSTAL BLAST (45). The two identified PCR fragments [Pf1-K2] and [E2-K2] were described, respectively, as *appA2* and *appA2* in the following text. For comparative purposes, the *appA* gene  
25 was amplified from *E. coli* BL21 (DE3) using the primers [E2-K2]. The PCR reactions and the resulting fragments were processed as described above.

*Subcloning and construction of expression vectors.* The PCR products [E2-K2] and [Pf1-K2] were cloned into pGEM®T-easy vector (Promega) according to the manufacturer instructions and transformed into TOP10F to screen  
30 for positive colonies. The isolated *appA2* and *appA* fragments were inserted into the pPICZ $\alpha$ A (Invitrogen, San Diego, CA) at the *Eco*RI and *Kpn*I sites, as described by the manufacturer instruction. The constructs were transformed into

- 19 -

TOP10F cells which were plated on LB medium containing 25 µg zeocin/ml. The positive colonies were then grown to prepare DNA for transformation.

*Yeast transformation and expression.* *Pichia pastoris* strain X33 (Invitrogen) were grown in YPD medium and prepared for transformation, according to the manufacturer instructions. Two µg of plasmid DNA was linearized using *Bgl*II and then transformed into *Pichia* by electroporation. After incubation for 3 h at 30°C in 1 M sorbitol without agitation, cells were plated in YPD-zeocin agar medium to screen integration of the transformed gene into the 5' AOX1 region of the host chromosomal DNA. After 2 days, transformants were incubated in minimal media with glycerol (GMGY medium) for 24 h. After the culture reached a density of about  $2.5 \times 10^8$  cells/ml ( $OD_{600} = 5$ ), the cells were spun down (3500g, 5 min) and then suspended in 0.5% methanol medium (GMMY) to induce the phytase gene expression.

*RNA quantification.* Total RNA was extracted from the *appA2* transformants at different times after induction. The RNA was separated in 1% formaldehyde-agarose gel, transferred onto Hybond N+ membrane (Amersham Pharmacia Biotech, Piscataway, NJ) by capillary blotting and UV cross-linked for 2 min. The membrane was then pre-hybridized for 4 h at 42°C. The probe was the *appA2* [E2-K2] PCR fragment, and was labeled with [ $\alpha$ - $^{32}$ P]-dCTP (DuPont, Boston, MA) using Ready-To-Go™ DNA Labeling Beads (Amersham Pharmacia Biotech). The membrane was hybridized with the probe overnight at 42°C, and washed three times for 20 min at 25°C and twice at 50°C in 2X SSC (0.15 M NaCl, 0.015 M sodium citrate), 1% sodium dodecyl sulfate (SDS), and finally twice at 50°C in 0.2X SSC, 0.1% SDS. The autoradiogram was produced by exposing the membrane to an intensifying screen of BAS-III FUJI Imaging plate (Fuji, Japan) for 10 h and quantified using a Bio-Imaging Analyzer (Kohshin Graphic Systems, Fuji, Japan). Results were normalized by the relative levels of 18S rRNA.

*Purification of the expressed enzymes.* All operations were carried out at 4°C. Both expressed r-*appA* and r-*appA2* enzymes, and the r-*phyA* phytase expressed in *A. niger* (kindly provided by BASF, Mt. Olive, NJ), were suspended in 50 mM Tris-HCl, pH 7 with 25% saturation of ammonium sulfate. The suspension was then centrifuged at 25,000g for 20 min. The supernatant was

- 20 -

mixed with 75% saturated ammonium sulfate under agitation for 12 h, and the mixture was centrifuged at 25,000g for 20 min. The pellet was then suspended in 10 ml 25 mM Tris-HCl, pH 7 and dialyzed overnight against the same buffer. The dialyzed sample was loaded onto a DEAE-Sepharose column (Sigma) equilibrated with 25 mM Tris-HCl, pH 7. After the column was washed with 200 ml of the same buffer, the bound phytase was eluted with 1 M NaCl in 25 mM Tris-HCl, pH 7. Three fractions exhibiting the highest phytase and acid phosphatase activities were pooled and dialyzed against 25 mM Tris-HCl, pH 7.5 overnight for the following studies.

- 10        *Electrophoretic analysis.* Protein concentration was measured by the Lowry's method (21). Non-denaturing gel electrophoresis and SDS-PAGE (15%) were performed as described by Laemmli (22). Proteins in SDS-PAGE were stained with Coomassie brilliant blue R-250. Acid phosphatase or phytase activity in bands of the non-denaturing gel was detected as described previously (17).
- 15        After electrophoresis, the gel was incubated for 20 min at 25°C in 0.2%  $\alpha$ -19 naphtylphosphate (or sodium phytate), 0.1% Fast Garnet GBC salts, 1 mM CaCl<sub>2</sub>, and 0.5 M Tris-HCl buffer pH 7.0.

- Deglycosylation of the enzymes.* Deglycosylation of r-appA2 was done using 0.3 IU of endoglycosidase H<sub>f</sub> (Endo H<sub>f</sub>) for 4 h at 7°C according to the manufacturer instructions (New England Biolabs, Beverly, MA). The
- 20        deglycosylated proteins were analyzed in a 15% SDS-PAGE as described above.

- Enzyme properties and hydrolysis of phytate phosphorus in soybean meal.* Phytase activity at different pH was determined at 33°C, using three different buffers. The temperature optimum for each enzyme was determined at its optimal
- 25        pH. The  $K_m$  and  $V_{max}$  values for r-appA2 and r-appA were determined at the optimal pH of each enzyme and 37°C. Hydrolysis of phytate phosphorus by r-appA2 was compared with that of r-appA and r-phyA. Different amounts of the purified enzymes were incubated with 1 g soybean meal in a 5 mL buffer (10 mM HCl or 0.2 M citrate) at their respective optimal pH (2.5 for r-appA, 3.5 for r-
- 30        appA2, and 5.5 for r-phyA) at 37°C for 2 h. The released inorganic phosphorus was determined as previously described (25). Thermostabilities of these three enzymes were compared. Each of the enzymes (2 mg/ml) was diluted 1:200 in 0.2 M sodium citrate, pH 5.5, and incubated for 20 min at 25, 37, 55, 65, 80 and

- 21 -

100°C. The samples were placed on ice for 30 min and the remaining phytase activity was measured at 37°C.

*Statistical test employed.* The Mann-Withney U-test was used for all the statistical evaluations (46).

5

**Example 8 - Bacterial Colony Screening and Identification.**

A total of 93 colonies were isolated. Over 70 colonies had intracellular phytase activity less than 500 U/g protein, and 6 colonies had activities greater than 1,000 U/g protein. Colony 88 demonstrated the highest phytase activity (2,927 U/g protein), with an acid phosphatase activity (1,391 U/g protein). Thus, it was chosen for further experiments. The production of phytase and acid phosphatase activities by the colony was greater in Sweet E than LB broth and greater at anaerobic than aerobic conditions. Subsequently, the colony was identified as a gram negative *E. coli*. This was confirmed, in particular, by the substrate fermentation profile.

15

**Example 9 - Cloning and Sequencing of the Pig *E. coli* appA2 Gene.**

A 1482 bp (whole) and a 1241 bp (coding region) fragments were amplified from the genomic DNA of Colony 88 (Figure 6). Except for the *E. coli* *appA* gene and the *Bacillus* phytase gene, no significant sequence homologies were found in the GenPro databank (version 61), GeneBank or EMBL databases using BLAST program. The whole nucleotide sequence had 47 and 95% homology with the *Bacillus* sp. DS 11 phytase gene (GeneBank accession number 3150039) and *E. coli* *appA*, respectively. In spite of such a high nucleotide sequence homology, there were distinct differences between *appA* and *appA2* and their encoding polypeptides. First, seven amino acids were different in the deduced peptide sequences: one in the signal peptide, L4F; six in the coding region, S102P, P195S, S197L, K202N, K298M, and T299A. Second, the 73 bp untranslated region, located between the lead sequence and coding region, was shorter by 6 bp than that of *appA*. However, the three putative N-glycosylation sites were still located in the coding region at the same place. The DNA fragment

20

25

30

- 22 -

was sequenced for five times to verify these differences. Compared with *phyA*, *appA2* had only a 19% of amino acid sequence homology. The sequence has been transmitted to GeneBank data library with the accession number 250016.

5    **Example 10 - Expression of *appA2* in *Pichia pastoris*.**

A total of 42 transformants were analyzed for phytase and acid phosphatase activities at various intervals. Three days after methanol induction, 13 transformants produced phytase activity from 18 to 114 U/mL of medium and acid phosphatase activity from 7 to 42 U/mL. Meanwhile, 22 *appA* transformants expressed phytase activity from 25 to 130 U/mL and acid phosphatase activity from 59 to 85 U/mL. The *appA2* transformant that demonstrated the highest activities was used in the expression time course (Figure 7) and other studies. The *appA2* mRNA level reached the peak at 4 h (Figures 7 and 8), remained high until 12 h, and thereafter declined significantly. No *appA2* mRNA signal was detected in the control cells. Both the extracellular phytase and acid phosphatase activities produced by the transformant increased sharply between 0 and 24 hours. Thereafter, the acid phosphatase activity remained nearly unchanged while phytase activity increased much less over time than that at the earlier phase.

20

**Example 11 - Characterization of the Purified Enzymes.**

The specific phytase activity of the purified r-*appA2*, r-*appA*, and r-*phyA* enzymes was 28.9, 30.7, and 19.8 U/mg protein, respectively. The purified r-*appA2* demonstrated a higher affinity for sodium phytate than pNNP, as shown by the  $K_m$  and  $V_{max}$  values (Table 1). When sodium phytate was used as the substrate, the pH curve was significantly different among the three enzymes.

25

**TABLE 1**

Kinetic parameters of the purified r-appA and r-appA2 expressed in *Pichia pastoris*

	r-appA	r-appA2
$K_m$ , mM		
Sodium phytate	1.03	0.66
p-NPP	2.26	1.43
$V_{max}$ , $\mu\text{mole min}^{-1} \text{mg}^{-1}$		
Sodium phytate	89	117
p-NPP	310	340

5

The pH optimum was between 2.5 and 3.5 for r-appA2, 2.5 for r-appA, and 2.5 and 5.5 for r-phyA phytase (Figure 9). However, the two *E. coli* enzymes demonstrated the same pH optimum (2.5) for the substrate pNPP. In addition, both r-appA and r-appA2 had the same temperature optimum (55°C) which was slightly lower than that of r-phyA. These two enzymes also had very similar thermostabilities of phytase activity which were slightly higher between 37 and 60°C and lower between 65 and 100°C than that of *r-phyA*. The acid phosphatase activity of r-appA2 that remained after different temperature treatments was shown in the non-denaturing gel, as a unique band of 71 kDa (Figure 10). The activity was largely or completely lost at 65 or 80°C, but somehow recovered partially at 100°C. When the three purified recombinant enzymes were incubated with soybean meal, r-appA2 protein released significantly more phosphorus from phytate than the other two enzymes (Figure 11).

#### 20 **Example 12 - Effects of Deglycosylation on Enzyme Properties.**

After the three purified enzymes were treated with  $\beta$ -mercaptoethanol and Endo H<sub>f</sub>, more than 90% of their activities for both sodium phytate and pNPP were lost. But, Endo H<sub>f</sub> alone had no significant effect on their catalytic activities.

25 Deglycosylation of r-appA2 resulted in a single band with an apparent Mr of 46.3

- 24 -

kDa from three distinguished bands for the glycosylated forms with apparent  $M_r$  of 50.5, 53 and 56 kDa. This gave a range of glycosylation for r-appA2 between 8.3 and 17.3%.

In the above examples, a phytase-producing *E. coli* strain was isolated  
5 from the pig colon content. Using primers based on the *E. coli* pH 2.5 acid  
phosphatase gene (*appA*) described by Dassa et al. (18), a 1487 bp DNA fragment  
was amplified from the genomic DNA of the strain. This fragment, designated as  
*appA2*, encodes a protein of 433 amino acids with 3 putative N-glycosylation  
sites. The deduced peptide contains both the N-terminal motif (RHGXRRP,  
10 position: 38-44) (SEQ. ID. No. 7) and the C-terminal motif (HD, position: 325-  
326), characteristic for histidine acid phosphatases (8). In addition, there is a lead  
sequence of 30 amino acids and an untranslated region of 73 bp. Among the  
available sequence databases, only the *E. coli appA* pH 2.5 acid phosphatase and  
the *Bacillus sp.* DS11 phytase genes share some homology with *appA2* (95% and  
15 47% in nucleotide sequence, respectively). In spite of the high homology between  
*appA* and *appA2*, there are distinct differences between these two genes and their  
respective proteins. First, seven amino acids differ between the two deduced  
polypeptide sequences: one within the signal peptide and six in the coding region.  
Second, the 73 bp untranslated region between the lead sequence and the coding  
20 region was shorter by 6 bp than that of *appA*. All those differences have been  
confirmed by five repetitive nucleotide sequencing analysis.

More importantly, when these two genes are transformed into the same  
host, *Pichia pastoris*, the expressed proteins r-appA and r-appA2 show differently  
biochemical characteristics. Although both exhibit the same pH optimum of 2.5  
25 for pNNP, r-appA2 has a broad pH optimum between 2.5 and 3.5 while r-appA  
had it at 2.5 for sodium phytate. Compared with r-appA, the r-appA2 has a higher  
affinity for both substrates, as shown by the lower  $K_m$  and higher  $V_{max}$  values, and  
releases more phosphorus from phytate in soybean meal *in vitro*. Thus, the  
catalytic function of r-appA2, towards phosphorus hydrolysis from phytate or  
30 phosphate, seems to be better than that of r-appA. Apparently, the six amino acid  
exchanges in the polypeptide may not be not just a polymorphism of the enzyme,  
but rather responsible for the observed kinetic differences. Thus, it seems  
reasonable to state that the *appA2* is a different gene from *appA*, although a more

- 25 -

defined structural analysis is needed to elucidate the relationship between specific amino acid exchanges and functional alterations of these two enzymes. It will be necessary to produce the crystal of both enzymes first for future structural studies (27).

5           Previously, several *E. coli* enzymes have been reported to hydrolyze pNNP or sodium phytate (18, 19, 39-41). Greiner et al. (39) characterized two *E. coli* phytases (P1 and P2). They found that the purified *E. coli* phytase P2 shares a great identity with the *E. coli* pH 2.5 acid phosphatase in the N-terminal sequence, chemical properties, and kinetics. Thus, they suggested that these two enzymes  
10           might be the same protein and the *E. coli* pH 2.5 acid phosphatase should better be regarded as a phytase. Indeed, both r-appA acid phosphatase and r-appA2 are not only able to hydrolyze phytate in the pure chemical form or in the natural food, but also have a higher affinity for sodium phytate than pNNP. Therefore, these two enzymes could be classified as phytases.

15           Compared with the purified phytase P2 (39), r-appA2 has the same optimum temperature (55°C) and similar molecular mass after deglycosylation (46.3 kDa). Based on the SDS-PAGE and non-denaturing gel analyses, the protein is also monomeric. However, r-appA2 has a more acidic pH optimum (2.5 to 3.5 vs. 4.5 for P2) and contains 8 to 14 % of sugar moieties because of the N-  
20           glycosylation in *Pichia*. Deglycosylation of r-appA2 with Endo H<sub>f</sub> reduces the molecular size but has a minimal effect on its activity. In contrast, when the protein is incubated with P-mercaptoethanol and Endo H<sub>f</sub>, the phytase and acid phosphatase activities of r-appA2 are considerably reduced. This indicates that disulfide bonds are required for its phytase activity as previously shown for the *A.*  
25           *ficuum* phytase (47).

          Although preferred embodiments have been depicted and described in detail herein, it will be apparent to those skilled in the relevant art that various modifications, additions, substitutions, and the like can be made without departing from the spirit of the invention and these are therefore considered to be within the  
30           scope of the invention as defined in the claims which follow.

What is claimed:

1. A phosphatase fragment having improved phytase activity comprising:

5 a fragment of phosphatase having increased phytase activity produced by treating phosphatase with a protease.

2. The phosphatase fragment according to claim 1, wherein the phosphatase is a microbial phosphatase.

10

3. The phosphatase fragment according to claim 2, wherein the microbial phosphatase is an *Escherichia coli* phosphatase.

4. The phosphatase fragment according to claim 2, wherein the  
15 microbial phosphatase is AppA.

5. The phosphatase fragment according to claim 2, wherein the microbial phosphatase is AppA2.

20 6. The phosphatase fragment according to claim 1, wherein the protease is pepsin.

7. The phosphatase fragment according to claim 1, wherein the phosphatase is expressed in yeast.

25

8. The phosphatase fragment according to claim 7, wherein the yeast is *Pichia pastoris*.

9. The phosphatase fragment according to claim 7, wherein the yeast  
30 is *Saccharomyces cerevisiae*.

10. The phosphatase fragment according to claim 1, wherein the fragment is encoded by a recombinant gene comprising:

- 29 -

a promoter;  
a coding region encoding the phosphatase fragment according to claim 1;  
and  
a terminator.

5

11. An improved animal feed comprising the phosphatase according to claim 1.

12. A recombinant gene encoding a phosphatase fragment having  
10 improved phytase activity, comprising:  
a promoter;  
a coding region encoding the phosphatase fragment according to claim 1;  
and  
a terminator.

15

13. A vector carrying the gene according to claim 12.

14. A host cell transformed with the vector according to claim 13.

20 15. The host cell according to claim 14, wherein the host cell is yeast.

16. The host cell according to claim 15, wherein the yeast is *Pichia pastoris*.

25 17. The host cell according to claim 15, wherein the yeast is *Saccharomyces cerevisiae*.

18. A method of increasing the phytase activity of phosphatase,  
comprising:  
30 treating the phosphatase with a protease.

19. The method according to claim 18, wherein the phosphatase is a microbial phosphatase.

- 30 -

20. The method according to claim 19, wherein the microbial phosphatase is an *Escherichia coli* phosphatase.
- 5 21. The method according to claim 19, wherein the microbial phosphatase is AppA.
22. The method according to claim 19, wherein the microbial phosphatase is AppA2.
- 10 23. The method according to claim 18, wherein the protease is pepsin.
24. The method according to claim 18, wherein the phosphatase is expressed in yeast.
- 15 25. The method according to claim 24, wherein the yeast is *Pichia pastoris*.
26. The method according to claim 24, wherein the yeast is
- 20 *Saccharomyces cerevisiae*.
27. A phosphatase having improved phytase activity, comprising:  
a polypeptide having an amino acid sequence as shown in SEQ. ID No. 1.
- 25 28. The phosphatase according to claim 27, wherein the phosphatase is expressed in yeast.
29. The phosphatase according to claim 28, wherein the yeast is *Pichia pastoris*.
- 30 30. The phosphatase according to claim 28, wherein the yeast is *Saccharomyces cerevisiae*.

- 31 -

31. The phosphatase according to claim 27, wherein the phosphatase is encoded by a recombinant gene comprising:

a promoter;

a coding region encoding the phosphatase according to claim 27; and

5 a terminator.

32. An improved animal feed comprising the phosphatase according to claim 27.

10 33. An isolated nucleic acid molecule encoding the phosphatase according to claim 27.

34. A vector carrying the nucleic acid molecule according to claim 33.

15 35. A host cell transformed with the vector according to claim 34.

36. The host cell according to claim 35, wherein the host cell is yeast.

20 37. The host cell according to claim 36, wherein the yeast is *Pichia pastoris*.

38. The host cell according to claim 37, wherein the yeast is *Saccharomyces cerevisiae*.
